

## Natural avalanches on way to Mt. Blackmore\_1

"Noted several avalanches (NW aspect ~ 8800') off of Elephant that traveled quite far into the trees where the summer trail typically runs, all appear to be new snow, D1- D2 in size, average 2' crowns, running on old/new interface from Feb 2. They appear to have run midstorm, sometime yesterday (photos 1,2,3). Above 9000', W Winds were crafting fresh wind slabs that were most reactive on a midstorm crystal/density change that buried a layer of stellars ~ 1' deep in shallower spots, topped with denser snow."
